Measurement Information Specification Design Progress Version 2.1

Information Need Description	
Information	Evaluate the status of the software design activity and see whether design activities
Need	are being completed as scheduled.
Information	Schedule and Progress
Category	

Measurable Concept	
Measurable	Work Unit Progress
Concept	

Entities and Attributes	
Relevant Entities	Design unit schedule
	 Configuration management records of completed and approved design units
Attributes	Planned design units
	Status of design units

Base Measure Specification	
Base Measures	 Design units planned to be completed each period (design units planned) Design units that have completed design (design units complete)
Measurement Methods	Count the cumulative number of design units planned to be completed to date. Count the number of approved design units under configuration management.
Type of Method	Objective
Scale	Integers from zero to infinity
Type of Scale	Ratio
Unit of	Design unit
Measurement	

Derived Measure Specification	
Derived	Percent of design units completed (percent complete)
Measure	
Measurement	Divide design units complete by design units planned for each period and multiply
Function	by 100.

	Indicator Specification		
Indicator	Design Completion: Graph the two base measures (design units planned and design units complete) over time; also, include a data table with the derived measure (percent complete). Software Design Progress		
Description and Sample	100 80 60 40 20 Jan Feb Mar Apr May Jun Jud Aug Sep Oct Nov Dec Jan Feb		
	101 101 101 101 101 101 101 101 101 101 101 101 101 101 101 102 102		
Analysis Model	The two lines should be very close together, and the derived measure, percent complete, should stay close to 100%.		
Decision Criteria	A design completion result of 90% or less, or a percentage complete that declines during three consecutive periods, should be further investigated, and a replan may be required.		
Indicator Interpretation (sample chart)	This indicator tells the project manager that design progress has been behind the original plan for the last four months. While corrective actions were taken during each of the four prior months, based on the established decision criteria for the indicator, they did not solve the problem. Therefore, in May, a replan of the overall design activity was conducted (plan 2), and this information was added to the chart. The replan resulted in extending the design schedule by two months.		

Data Collection Procedure (for each Base Measure) Complete this section for each base measure listed on the previous page.	
Frequency of Data Collection	 Once from initial plan, and updated whenever a revision to the design unit completion plan occurs. Biweekly
Responsible Individual	 Software manager provides plans; measurement analyst validates data. Measurement analyst collects data from CM representative.
Phase or Activity in which Collected	Design phase only
Tools Used in Data Collection	Excel (planning data) CM system (actual data)
Verification and Validation	 Total number of units are compared to Software Development Folders (SDFs) to ensure total is correct. Slope of curve is reviewed to ensure it is achievable. Start and end dates are compared to Master Schedule to ensure compatibility. Actuals are compared to periodic QA spot-checks to ensure units are complete.
Repository for Collected Data	PSM Insight

Data Analysis Procedure (for each Indicator)	
Frequency of	Biweekly
Data Reporting	
Responsible	Measurement analyst
Individual	
Phase or Activity	Design phase only
in which	
Analyzed	
Source of Data	PSM Insight
for Analysis	
Tools Used in	Straight line trend lines may be used to estimate completion.
Analysis	
Review, Report,	Reported at biweekly software IPT meetings to supplier management and design
or User	team leads.

	Additional Information	
	As part of the feasibility analysis process, the rate of planned progress should be reviewed to ensure it is reasonable and not unusually steep. In addition, the plan should be checked to ensure it reflects the total number of units estimated for the system.	
Additional Analysis Guidance	During performance analysis, in addition to using the decision criteria, any major changes in the rate of actual progress should be investigated for the root cause. Once an actual trend line is established, it is difficult to modify the rate of completion unless a corrective action is applied or the process is altered. Also, a more detailed analysis is often required when actual progress lags behind planned progress. For example, analyzing progress by subsystem may help identify which components are most behind schedule. Staffing levels, experience levels, changes in scope, and quality problems may all be contributors to lack of progress and should be investigated.	
	This is easier to collect if a disciplined process is in place, with documented entrance or exit criteria. For example, a project might require a design walkthrough to occur prior to turnover of the design to configuration management. This helps ensure that all units are completed using similar criteria and reduces rework.	
	Similar measures are often used for other phases (e.g., code progress, test progress).	
Implementation Considerations	Work unit progress measures are typically collected and reported only for a specified project time period, i.e., during the time that the design is being developed. Reporting should be at least monthly and possibly weekly for smaller, shorter projects and where data is available weekly. The "owners" of the work units being measured (e.g., the designers) are usually responsible for data delivery. Unit completeness measures are only as good as the criteria used to determine whether a unit is complete.	
	The aggregation structure used is typically "component." For large systems with many hundreds of units, indicators should be able to show which areas of the system are having trouble with completion, as well as whether the system as a whole is on track.
